<p><b>Edmonds-Karp algorithm</b></p> <p>starting at <math>s</math></p>	<p><b>Idea:</b> In each iteration, use a shortest augmenting path, i.e. a path from <math>s</math> to <math>t</math> with the fewest number of edges. Can be found with BFS in time <math>O( E )</math>.</p> <table border="1"> <tr> <td>Insert from top ↓</td> <td></td> <td></td> <td><b>t=2</b></td> </tr> <tr> <td></td> <td></td> <td>d=1</td> <td>e=2</td> </tr> <tr> <td>Access from bottom ↑</td> <td><b>s=0</b></td> <td><b>b=1</b></td> <td><b>d=1</b></td> </tr> <tr> <td></td> <td></td> <td></td> <td>e=2</td> </tr> </table> <p>shortest augmenting path: s-d-t</p>	Insert from top ↓			<b>t=2</b>			d=1	e=2	Access from bottom ↑	<b>s=0</b>	<b>b=1</b>	<b>d=1</b>				e=2	
Insert from top ↓			<b>t=2</b>															
		d=1	e=2															
Access from bottom ↑	<b>s=0</b>	<b>b=1</b>	<b>d=1</b>															
			e=2															
<p>with vertex restrictions</p>	<p><b>Restriction:</b> Maximum flow through vertices is restricted.  <b>Solution:</b> Add additional vertex before the restricted vertex and add new edge with weight = vertex restriction. Direct all ingoing edges to the new vertex. e.g. <math>b</math> by 3:</p>																	
<p>Distribution problem reduced to Max-Flow</p>																		
<p>Bipartite matching</p>	<p>Make edges directed. Add source and sink vertices <math>s</math> and <math>t</math> with corresponding edges. Set all edge weights to 1. Find integer maximum flow with Ford-Fulkerson algorithm.</p>																	

<p>Var: <b>Max-Flow</b> <b>Min-Cut</b></p>	<p><b>Goal:</b> Find a minimum partition of the vertex set which divides S and T into two sets.  <b>Applications:</b> Redundancy in networks, reliability in telecommunication, military strategy, optimizing traffic systems</p> <p>The maximum st flow equals the minimum value of all (exponentially many) possible st-cuts.</p>	
--	---	--

<p>Var: <b>Min-Cost</b> <b>Max-Flow</b></p> <p>harder</p>	<p>Each edge <math>e</math> has capacity <math>c(e)</math> and cost <math>cost(e)</math>  <b>Goal:</b> Find the maximum flow that has the minimum total cost</p>	
---	--	--

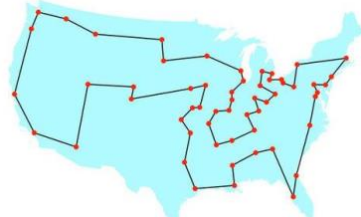

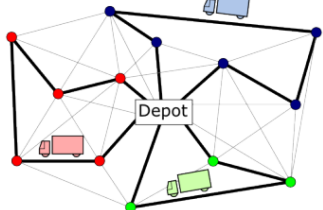

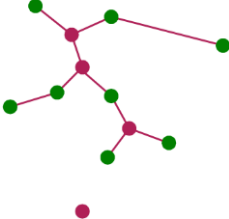

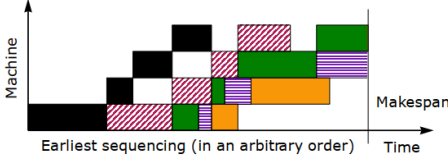

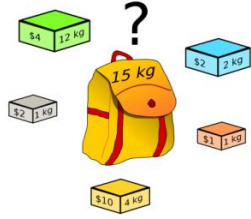

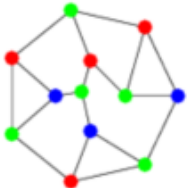

Often there are several possible maximum flows with a cost per flow unit.  
**Solution:** Extend Ford-Fulkerson algorithm to take cost criterion into account.

s-b-d-t	s-b-e-t	s-c-e-t	
$2 \cdot 6 = 16$	$1 \cdot 5 = 5$	$1 \cdot 4$	capacity = 4 cost = 21

Until now, we just used the Ford-Fulkerson algorithm with additionally annotating the costs. Now, look for cycles, respecting the capacities. This does not change the total flow from s to t, but decreases the total cost.

s-c-e-b-s	
capacity $1 \cdot (3-4)$	
s-b-e $\rightarrow$ s-c-e	
	capacity = 4 new cost = 20

# COMBINATORIAL PROBLEMS - NP-CLASS

<p><b>TSP</b> <b>Traveling Salesperson Problem</b></p> <p><math>O((n - 1)!)</math></p>	<p><b>Input:</b> <math>n</math> cities, <math>d_{ij}</math> distances matrix between cities <math>i</math> and <math>j</math>.  <b>Goal:</b> Find the shortest tour passing exactly once in each city.</p> $\sum_{i=1}^{n-1} d_{p_i p_{i+1}} + d_{p_n p_1}$ <p><b>Application:</b> Network Design, pipes, cables, chip design, ...  <b>Algorithms:</b> Nearest Neighbour (=Greedy), MST-based  <math>MST &lt; TSP \leq 2 * MST</math></p>

<p>Var: Job Shop Problem</p>	<p>Introduction for new employees</p>	
<p><b>Knapsack Packing Problem</b></p>	<p><b>Input:</b> <math>n</math> items each with a weight <math>w_i</math> and a value <math>v_i</math>, maximum weight capacity <math>W</math>  <b>Goal:</b> maximize the value with respect to maximum weight  <b>Algorithms:</b> Naive Greedy, Smarter Greedy                  simplest ILP (only one inequality) but NP-complete</p>	
<p><b>Santa Claus Problem</b></p>	<p><b>Input:</b> <math>n</math> item with location on earth and weight, max carry weight  <b>Goal:</b> Minimize the weighted distance to deliver all items to the given location</p>	
<p><b>Vertex Coloring</b></p>	<p><b>Input:</b> Graph  <b>Goal:</b> Find an assignment of colors to each vertex such that no edge connects two identically colored vertices.  <b>Variants:</b> Minimize the number of colors  <b>Algorithm:</b> First Fitting Color, Decreasing Degree</p>	

<p><b>QAP Quadratic Assignment Problem</b></p>	<p><b>Given:</b> Set of activities and locations along with the flows between activities and the distances between locations  <math>d_{ij} \in D</math>: distance matrix  <math>f_{ik} \in F</math>: flow matrix  <math>x_{ij}</math>: 1 if activity is assigned to location j, 0 otherwise  <b>Goal:</b> assign each activity to a location to minimize total cost</p> $\min z = \sum_{i,j=1}^n \sum_{k=1}^n d_{ij} f_{jk} x_{ij} x_{hk}$	
<p><b>Neighborhoods</b></p>	<p>- swap 2 locations of 2 facilities <math>O(n^2)</math>                  - swap locations of k=3,4,... facilities <math>O(n^k)</math></p>	
<p><b>Post office problems</b></p>	<p><b>Goal:</b> Find the next post office (or ATM nowadays) in a city from your location.  <b>Solution:</b> Use Voronoi diagram</p>	
<p><b>Exact cover</b></p>	<p><b>Given:</b> Subset <math>U_i, i = 1..n</math> of a base set M  <b>Find:</b> Exact cover (if one exists), i.e. a choice of sets <math>U_i</math> such that their union is m and no element is contained in more than one of these sets.                  Optimization: Find a choice of sets <math>U_i</math> such that their union is M and as few element as possible are contained in <math>U_i</math>.</p>	
<p><b>n queens problem</b></p>	<p><b>Goal:</b> Place n queens on a <math>n \times n</math> board such that no two queens can capture each other.</p>	

# HEURISTICS

## General

<b>Heuristic</b>	A heuristic method is based on knowledge acquired by experience on a given problem. They are opposed to exact algorithms. Heuristic methods do <b>not necessarily provide the best solution</b> , but need <b>reasonable time</b> .	
<b>Meta-Heuristic</b>	A meta-heuristic is a limited <b>set of concepts</b> that can be applied to a large set of combinatorial optimization problems and that allow creating new heuristic methods. It provides support for designing heuristic methods, based on knowledge acquired by designing heuristic method for various problems.	
Trajectory-based	Start with a solution and improve it continuously by exploring its "neighborhood". We obtain a trajectory through the solution space.	
Population-based	An evolving population of (partial) solutions, whose members evolve and adapt individually to the problem and are searching for the optimum. Problem specific information can be <b>exchanged</b> between the members of the population, and can be <b>passed on</b> to descendants.	
<b>Neighborhood</b>	Too small: get stuck quickly without exploring Too large: computation time to high	

## Heuristics

For TSP:

<b>Nearest Neighbour</b> (=Greedy)	Start from city 1. Repeat: Go to the nearest city not yet visited, until all visited.	
<b>Best Global Edge</b> (=Greedy)	Initial $S: \emptyset$ $R$ : Set of edges that can be added to $S$ such that: No cycle is created, no vertex with degree $> 2$ is created $c(S, e)$ : weight of edge $e$ (this is independent from $S$ )	
<b>Maximum Regret</b> (=Greedy)	$S = \{1\}$ $R$ : Set of cities not yet visited $c(S, e) =$ Regret of not going to $e$ from $i$ Choose the largest $c(S, e)$	
<b>Best Insertion</b> (=Greedy)	$S =$ Tour on 2 cities $R$ : Set of cities not yet visited $c(S, e) =$ Minimum insertion cost of city $e$ between 2 cities Choose the smallest $c(S, e)$	

For Vertex Coloring

<b>First Fitting Color</b> (=Greedy)	Select an ordering of the vertices $s = \emptyset$ // set of already colored vertices $R = V$ // set of vertices not colored yet $C(s, e)$ // set of colors that can be assigned to a vertex (sorted) Choose first color in $C(s, e)$	
<b>Decreasing Degree</b> (=Greedy)	sort the vertices by decreasing order of degree Remaining is identical to first fitting color	
<b><math>D_{satur}</math></b> (=Greedy)	choose the uncolored vertex with the highest "saturation degree", i.e. with the maximum number of different adjacent colors. Break ties by choosing the vertex with maximum degree.	

## Meta Heuristics

### Constructive

<b>Random Sampling</b> "or Building"	<b>Idea:</b> Generate a solution randomly, uniformly in the solution space <b>Advantages:</b> Simple, works good, easy to implement <b>Disadvantages:</b> bad solution quality, uniform distribution sometimes not trivial Sometimes not easy to find -> add penalty function	S = Random solution Repeat Find another solution randomly Use if better than S Until satisfied
<b>Greedy Construction</b>	<b>Idea:</b> Build element by element, by adding systematically the most appropriate ("best") element. Needs a cost function that measures the quality of adding element e to a partial solution S. Adding an element generally implies restrictions for the next elements to add. <b>Disadvantages:</b> too short-sighted Works optimally for: MST, Shortest Path, ...	R = E (set to add) Repeat Evaluate $c(S,e)$ for each $e \in R$ Choose $e'$ which optimizes $c(S,e)$ Add $e'$ to the partial solution S Remove from R all elements that cannot be added to S anymore. Until S is a complete solution
<b>Exhaustive Search</b>	<b>Idea:</b> Generate all feasible solutions and find the optimum <b>Advantages:</b> Guarantees to find an optimal solution Often easy to implement <b>Disadvantages:</b> The set of feasible solutions is often exponential -> takes too much time.	
<b>Pilot Method</b> $O(n^2)$ for TSP	<b>Idea:</b> Evaluate the quality of adding an element e to s by completing it to a full solution. The heuristic to complete a solution must be chosen, e.g. greedy + local search, ... <b>Remarks:</b> Time complexity is increased by the "pilot"	For all e that can be added to S Calc s+e with heuristic "pilot" Keep the best solution
<b>Beam Search</b>	<b>Idea:</b> Similar to exhaustive search, but define a beam width (e.g. 2) and browse depth. beam width = $\infty \rightarrow$ exhaustive with BFS	For each partial solution expand up to k depth keep the most promising

**Local Improvement**

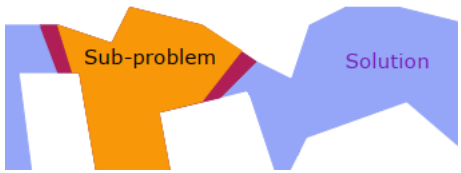

<p><b>Local Improvement</b> = Local Search = Hill Climbing</p>	<p><b>Idea:</b> Start with a given solution (with a constructive method) and find improvements <b>Neighbourhoods:</b> <b>Terminating:</b> fixed number, no improvement after x steps, when a target is reached</p>	<p>Repeat Try to find an improved solution Perform if found While An improvement is found</p>																																														
<p>Selection</p>	<p><b>First Improving Move</b> (takes the first move that improves the current solution)</p>	<p>While improving solution <math>s' = \text{new solution}</math> if <math>c(s') &lt; c(s)</math> <math>s = s'</math></p>																																														
	<p><b>Best Improving Move</b> (take the best move that improves the current solution)</p>	<p><math>\text{costOfBestNewSol} = a</math> for each move <math>m</math> in <math>M(s)</math> <math>s' = \text{new solution with } m \text{ applied}</math> if <math>c(s') &lt; \text{costOfBestNewSol}</math> <math>\text{costOfBestNewSol} = c(s')</math> <math>\text{bestMove} = m</math> apply <math>\text{bestMove}</math> to <math>s</math></p>																																														
<p>Neighbourhood</p>	<p><b>TSP:</b> search for intersections, 2/3/k-opt, or-opt (move a subchain of vertices somewhere else) -&gt; use a doubled chained list  <b>CVRP:</b> First fit, Random, Closest (customer, point of gravity, edge), lowest left capacity, change beginning  <b>Knacksack:</b> shift, invert, transpose(swap)</p>		<p><b>Connectivity:</b> A global optimum can be reached from any feasible solution <b>Low diameter:</b> Number of moves for linking any pair of solutions is small <b>Low ruggedness:</b> Limited number of local optima <b>Limited size:</b> Number of neighbour solutions is small <b>Easy to evaluate:</b> neighbour solution must be found without prohibitive computation</p>																																													
<p>Var</p>	<p>Always take best solution from neighborhood, even if this decreases target function. (+) to escape from local optima (-) might go back and forth (run into a cycle) (-) not monotone increasing</p>																																															
<p><b>Tabu Search</b> (=Local Search)</p>	<p><b>Idea:</b> Similar to hill climbing, but with some memory. Try to avoid steps that go back to previously visited solutions, or that undo the effect of previous steps. <b>Goal:</b> Promote diversity of the solutions explored, in particular to reduce cyclic behaviour and to escape from local optima. <b>Tabu list:</b> store last move / store last n moves / ... Allow invalid solutions but <b>penalize</b> them (fix or variable). <b>Tuning:</b> Learn tabu value (incr/decr or rand)</p>		<p>Start with a random solution Repeat Find a better solution Consider steps that ar not tabu Perform if better and update tabu list Until criteria reached</p>

<p>Var: <b>MMAS</b> MaxMin Ant System  one of the most successful</p>	<p><b>Changes:</b> Only the best ant updates the pheromone trails Maintains lower and upper bounds <math>\tau_{min}, \tau_{max}</math> for pheromone values <math>\tau_e</math> Pheromone is updated for the "best" solution, for the current iteration or "best-so-far" Update depends on the cost of the best solution</p>	
<p>e.g. for TSP</p>	<pre> <b>Standard parameter settings</b> <math>\alpha = 1, \beta = -2, \rho = 0.98, Q = 1, b = 20, m = problem\ size</math> <math>\tau_{min} = \dots, \tau_{max} = \dots, max\_iter = \dots</math> // Problem dependent  <b>Initialisation</b> <math>\tau_{ij} = \tau_{max}</math> for all arc <math>(i, j)</math>  <b>Repeat for</b> <math>max\_iter</math> iterations    <b>For each</b> ant <math>k = 1, \dots, m</math>     <math>s_k = \emptyset</math> // Solution built by ant <math>k</math>     Choose a city <math>i</math> at random // Current city : <math>i</math>     <b>Repeat, while</b> all cities have not been visited       <b>If</b> there is a city <math>j</math> not yet visited among <math>b</math> nearest neighbours of <math>i</math>         Choose a city <math>j</math> among them with probability proportional to <math>\tau_{ij}^\alpha \cdot d_{ij}^\beta</math>        <b>Else</b> Choose a city <math>j</math> not yet visited with maximum <math>\tau_{ij}^\alpha \cdot d_{ij}^\beta</math>       <math>s_k = s_k + (i, j)</math>       <math>i = j</math>       Improve solution <math>s_k</math> with a local search      <b>For all</b> arc <math>(i, j)</math> of the best tour <math>s^*</math> among <math>s_1, s_2, \dots, s_m</math>       <math>\tau_{ij} = \max(\tau_{min}, \min(\tau_{max}, (1 - \rho)\tau_{ij} + Q/Length(s^*)))</math>  <b>Return</b> The best tour found         </pre>	
<p>Important</p>	<p>There is no need that ants really follow a consecutive path -&gt; like they can fly</p>	

## Randomized Local Search

<b>Noising Methods</b>	Add a random noise when evaluating the moves with decreasing probability <b>Typical</b> Noise: standard deviation <b>Generalisation</b> of the next three	Repeat Apply randomly move Accept if it's better Accept worse according to noise
Var: <b>Threshold Accepting</b>	Accept all move deteriorating (=verschlechtern) the solution less than a given threshold	
Var: <b>Great Deluge</b>	Only accept solutions with a given minimal quality; increase level of quality (like a "flood")	
Var: <b>Simulated Annealing</b>	Similar to hill climbing, but allow non-improving moves. Probability: Fixed / decreasing over time / decreasing over time and depending on quality $\min \left\{ 1, e^{-\frac{f(x_i) - f(y_i)}{T_i}} \right\}$ If $f(x_i) \geq f(y_i)$ term gets $\geq 1$ and $y_i$ is accepted. If $T \rightarrow \infty$ , every solution $y_i$ will be accepted. If $T \rightarrow 0$ , only better solutions will be accepted <b>Advantages:</b> spend more time on good solutions	Start with random solution Repeat Apply randomly move Accept if it's better Accept with probability if worse
<b>Restarting</b>	When local search does not improve anymore, start a new local search from: - best solution so far (good solutions are close) - randomly generated (explore with large variety - GRASP) - modification of best solution (keep structure - VNS)	
Var: <b>GRASP</b> Greedy Randomized Adaptive Search Procedure	Input: $s^*$ best solution found so far	Repeat $s$ = minimal partial solution construct $s'$ from $s$ with greedy find optima $s''$ in neighbourhood if $f(s'') < f(s^*)$ $s^* = s''$
Var: <b>VNS</b> Variable Neighbourhood Search	<b>Idea:</b> Working with $p$ different neighbourhoods	Repeat Choose a randomly neighbourhood find local optima in these apply if better

**Decomposition Methods**

	Neighbourhood is too large to fully explore. Split problem in smaller problems, optimize local solutions	
<b>VLNS</b> Very Large Neighbourhood Search	<b>Idea:</b> Partially explore the large neighbourhood to find improvements <b>ILP:</b> fix value of subset and solve, repeat with other subset <b>Iterated Local Search:</b> randomly perturb (=stören) the best solution so far, and apply an improving method	
<b>POPMUSIC</b> Partial Optimization Metaheuristic under special intensification conditions	<b>Idea:</b> Decompose solution into parts, optimize several parts of the solution, repeat until optimized portions cover the entire solution space  <b>Difficulty:</b> Sub-problems may not be independent from one another	$S = s_1 \cup s_2 \cup \dots \cup s_p$ $O = \emptyset$ // already optimized parts Parameter $r$ // "nearest parts"  While $O \neq S$ Choose a seed part $s_i \notin O$ Create a subproblem $R$ composed of the $r$ "closest" parts Optimize subproblem $R$ If $R$ improved then set $O = O \setminus R$ else $O = O \cup s_i$
example	<b>Variables (example with VRP)</b> Part = Tour of one vehicle Distance = between centres of gravity Sub-Problem: A smaller VRP Optimization process: e.g. Tabu Search <b>Variables (example with TSP)</b> Part = a single city $c$ on a tour Distance = $r$ adjacent cities on the tour, immediately before/after $c$ Sub-Problem: solve TSP for the $r$ cities (e.g. exhaustive) Re-Combination: re-insert subtour in existing tour <b>Variables (example for permutation shop problem)</b> Part = a single job $x$ Distance = take $x$ as seed job and select $r$ jobs that are scheduled before and after $x$ Sub-Problem = Re-Schedule the selected job (use additional time constraints for start/end time -> still valid) Re-Combination: shift all jobs as much to the left as possible	

<p><b>Evolutionary Algorithms</b></p> <p><b>Genetic Algorithms</b></p>	<p><b>Idea:</b> Selection: Survival of the fittest (natural selection) Finite lifespan of individuals (generations). <b>Inheritance</b> of traits, info is passed on to descendants. <b>Recombination</b>, info is exchanged between parents. <b>Diversification</b> (by mutations). Population acquires and cultivates shared knowledge (culture, collective memory) Local development of populations (different cultures in different regions)</p>	<p>Choose a suitable encoding Start at random population Repeat Create next generation: - assign fitness to individuals - natural selection - choosing parents for reproduc. - recombination and mutation Until criterion satisfied</p>																				
<p>Terminology</p>	<p>An <b>individual</b> is a possible solution candidate. e.g. vector The <b>genes</b> are the individual entries of an individual. The <b>alleles</b> are concrete values which a gene takes, e.g.0/1 The <b>population</b> is the set of all individuals at a given time. A <b>generation</b> is the population at a specific point in time. The <b>genotype</b> is the encoded form of an individual. The <b>phenotype</b> is the decoded form of an individual, do not depend on encoding. Are the solution candidates. The <b>fitness function</b> is our quality measure for a solution.</p>																					
<p>1. Encoding</p>	<p><b>Desirable:</b> A small change in genotype corresponds to a small change in phenotype. -&gt; use gray code <b>Example:</b> Vector of n integer / binary vector / ...</p>	<p>standard: 00-01-10-11 (dist=1-2) gray: 00-01-11-10 (dist=1)</p>																				
<p>2. Replacement schemes</p>	<p><b>General replacement:</b> Replace all individuals <b>Strict elitism:</b> Keep only m best individuals <b>Weak elitism:</b> m best individuals are mutated <b>Delete-n:</b> Replace n random individuals <b>Delete-n-last:</b> Replace n worst individuals, keep others <b>Retirement home:</b> Store some for later procreation</p>																					
<p>3. Selection</p>	<p><b>Selection pressure</b> means that better individuals should have a higher chance of reproduction. <b>Strategy:</b> Increasing selection pressure - (Unbiased) Random selection - Random selection with bias on better individuals (roulette wheel) - Tournament selection</p>	<p>Better <b>exploration</b> when pressure is low Better <b>exploitation</b> when pressure is high</p> <p><b>Tournament selection:</b></p> <table border="1" data-bbox="976 1108 1476 1182"> <tr> <td>best</td> <td>2-nd</td> <td>3rd-best</td> <td>(k)-best</td> </tr> <tr> <td><math>p</math></td> <td><math>(1-p)p</math></td> <td><math>(1-p)^2p</math></td> <td><math>(1-p)^{(k-1)}p</math></td> </tr> </table> <p>The larger k, the higher the selection pressure</p>	best	2-nd	3rd-best	(k)-best	$p$	$(1-p)p$	$(1-p)^2p$	$(1-p)^{(k-1)}p$												
best	2-nd	3rd-best	(k)-best																			
$p$	$(1-p)p$	$(1-p)^2p$	$(1-p)^{(k-1)}p$																			
<p>4. Recombination</p>	<p>Crossing of individuals to exchange and pass advantageous properties. - one-point crossover - two-point crossover - uniform crossover - PMX (2-point with repair mechanism) - adjacency method</p>	<table border="1" data-bbox="976 1220 1484 1384"> <tr> <td></td> <td>1-point</td> <td>2-point</td> <td>uniform</td> </tr> <tr> <td>parent 1</td> <td>1011 110</td> <td>1011 000 001</td> <td>10110</td> </tr> <tr> <td>parent 2</td> <td>0010 011</td> <td>0010 110 100</td> <td>00101</td> </tr> <tr> <td>child 1</td> <td>0010 110</td> <td>1011 110 001</td> <td>10111</td> </tr> <tr> <td>child 2</td> <td>1011 011</td> <td>0010 000 100</td> <td>00100</td> </tr> </table>		1-point	2-point	uniform	parent 1	1011 110	1011 000 001	10110	parent 2	0010 011	0010 110 100	00101	child 1	0010 110	1011 110 001	10111	child 2	1011 011	0010 000 100	00100
	1-point	2-point	uniform																			
parent 1	1011 110	1011 000 001	10110																			
parent 2	0010 011	0010 110 100	00101																			
child 1	0010 110	1011 110 001	10111																			
child 2	1011 011	0010 000 100	00100																			
<p>5. Mutation</p>	<p>bit flip / position mutation / inversion</p>																					
	 <p>The diagram illustrates the flow from an 'old Population' (m items) to a 'new Population' (m items). It shows four main paths: 1) 'Elitism Bypass' where a percentage 'q%' of the best individuals from the old population are directly copied to the new population. 2) 'Direct Mutation' where a percentage 'r%' of individuals are selected (S) and mutated (M) before being added to the new population. 3) 'Recombination' where a percentage 's%' of individuals are selected (S) and recombined (R) to form offspring for the new population. 4) 'Recombination / Mutation' where a percentage 't%' of individuals are selected (S), recombined (R), and then mutated (M) before being added to the new population. 5) 'Random Generation' where a percentage 'u%' of individuals are randomly generated (RG) from a 'random selection out of pools' and added to the new population. A legend at the bottom defines S as selection, R as recombination, M as mutation, and RG as random generation. The total percentage of the new population is 100%.</p>
